ECONOMY

## *U.S. Economy Grew at 3.2% Rate in 3rd Quarter*

By THE ASSOCIATED PRESS NOV. 29, 2016

The United States economy in the third quarter grew at the fastest pace in two years, according to a revised report that showed stronger consumer spending than first estimated.

Sections

*Democracy Dies in Darkness*

Wonkblog

## U.S. economy grew at sluggish 0.7 percent in first quarter of 2017

By Ana Swanson and Max Ehrenfreund April 28

“...a measure for **standard of living**: average real **gross domestic product (GDP)** per capita”  
– Boston Fed

“**Productivity** is the most important determinant of the **standard of living**” – Forbes

**“The welfare of a nation can scarcely be inferred from a measurement of national income as defined [by the GDP.]”**

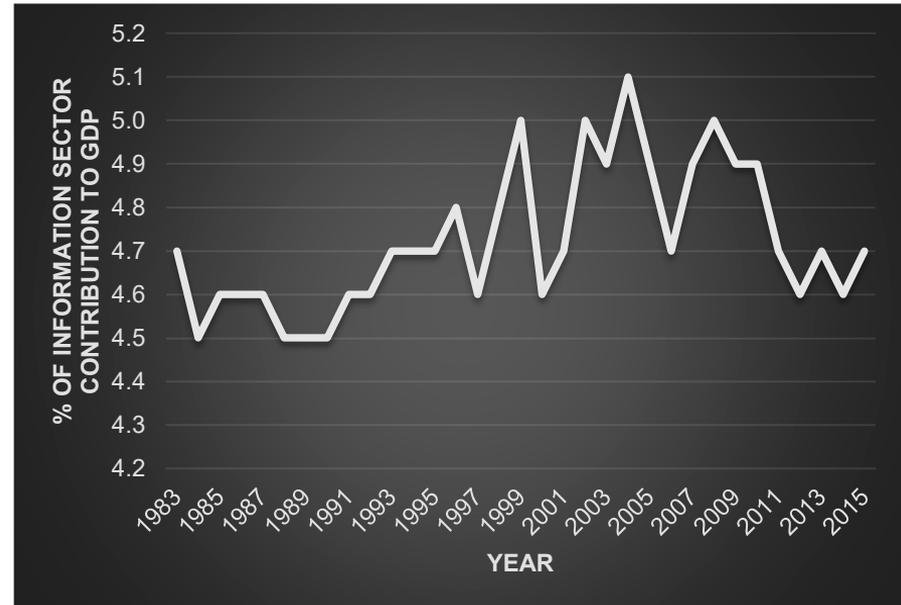

**- *Simon Kuznets, 1934***

**GDP is a measure of production, not well-being**

## Explosion of free digital goods

## Information goods as a share of GDP

# Our Approach

- **Estimate Consumer Welfare Directly**
- **Key techniques: Online Choice Experiments and Lotteries**
  1. Single Binary Discrete Choice Experiments
  2. Becker-DeGroot-Marschak Lotteries
  3. Best-Worst Scaling
- **Both with and without incentive compatibility**
- **At Massive scale**

# Key Findings

## 1. Choice experiments generate plausible demand curves

- Valuations are consistent across BDM lotteries, best-worst scaling and SBDC experiments
- But incentive compatible experiments often imply higher valuations

## 2. Median valuations

Search > email > maps > video > e-commerce > social media > messaging > music

## 3. Consumer surplus from Facebook in USA:

\$450/year for median consumer

## 4. This approach could be scaled up to numerous goods and services

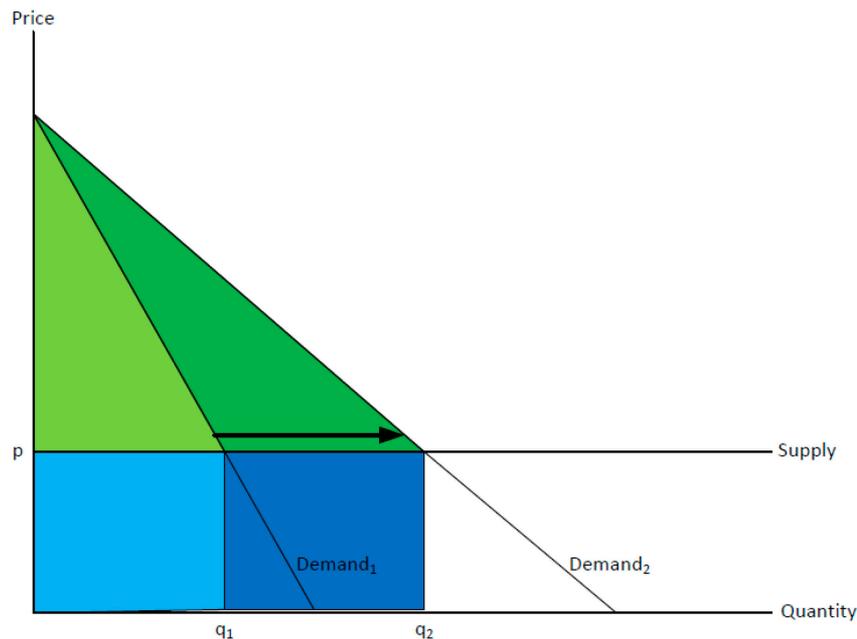

# **GDP vs. Consumer Welfare**

# $\Delta$ Production vs. $\Delta$ Consumer Surplus

## Case 1: Classic Goods

E.g. Automobiles, haircuts, food

GDP  $\uparrow$ , Consumer Surplus  $\uparrow$

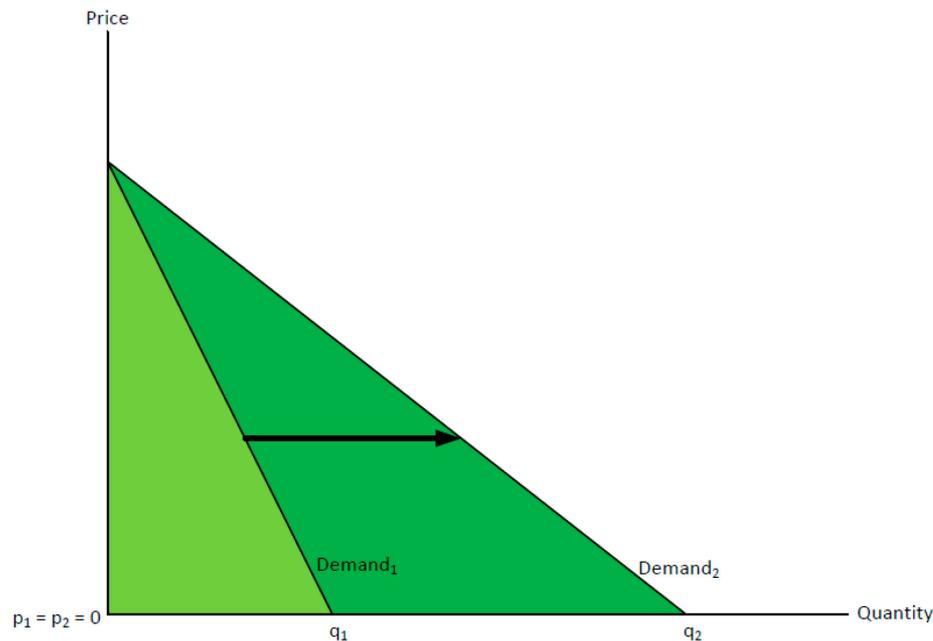

# $\Delta$ Production vs. $\Delta$ Consumer Surplus

## Case 2: Digital Goods

E.g. Increased use of free maps on smart phones or more digital photos;  
Special case: Free digital apps that never existed before

GDP no change,  
Consumer Surplus  $\uparrow$

# $\Delta$ Production vs. $\Delta$ Consumer Surplus

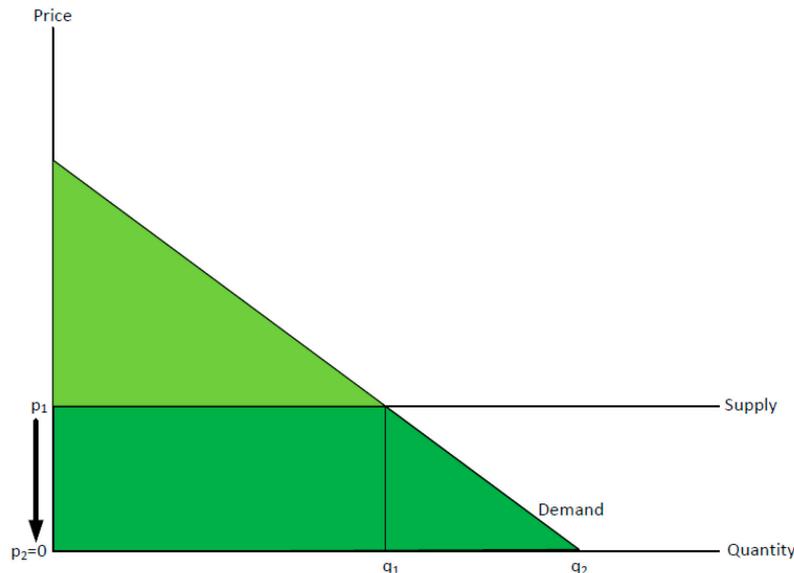

## Case 3: Transition Goods

E.g. Encyclopedia

(Wikipedia vs. Britannica)

Chemical photography to digital photography

GDP ↓, Consumer Surplus ↑

# What about producer surplus?

- **Nordhaus (2005): Innovators able to capture only 3.7% of social returns to innovation between 1948-2001**
  - If the share of producer surplus contribution to the total social surplus remains relatively stable, then consumer surplus would have to be scaled up by a small fraction
  - However, measuring simply the consumer surplus might be a concern if the producer surplus changes rapidly relative to the consumer surplus
    - Higher profit share recently?

# What about advertising revenue?

- 1. Advertising is an intermediate good, not included in GDP.**
  - Nakamura, Samuels and Soloveichik (2017) show how to account for advertising within GDP framework, find 0.07% increase in GDP/year
- 2. Advertising revenues are generally not proportional to consumer surplus and may reflect only a small share of it. (Spence and Owen 1977)**

# Approach & Results

# Discrete Choice Experiments

- **Common in marketing, transportation, price-setting, damages calculations, etc.**
  - Widely used in industry for new product introductions and pricings
  - Accepted as evidence in legal cases
    - BP oil spill (Carson, List et al, *Science* 2017)
    - Samsung vs. Apple (Hauser vs McFadden), etc.
- **Three variants**
  1. Single Binary Discrete Choice Experiments
  2. Best-worst scaling
  3. Becker-DeGroot-Marschak (BDM) lotteries
  - Each can be done with or without incentive compatibility

# Our Platforms for Choice Experiments

## 1. Lab in a University

- Includes incentive compatible studies (where we enforce choices)
- $N = 500$

## 2. Professional Survey Panel (Peanut Labs)

- 3 million active verified panelists, user quotas selected to represent internet users in US, good for longer surveys (BWS)
- $N = 5000$

## 3. Google Consumer Surveys

- Market research platform, good for short surveys (SBDC)
- $N = 200,000$

# Single Binary Discrete Choice (SBDC) Experiments

- **Ask consumers to make a single choice among two options:**
  - ❑ **Keeping the good**
  - ❑ **Give up the good and receive \$W in return**
- Prices \$W systematically varied between consumers
- Seek to reduce error by increasing quantity of responses
  - Aggregation of data leads to demand curves
  - Can be done with or without incentive compatible design

# Incentive Compatible SBDC Experiments

- **Randomly pick some respondents and fulfill their selection**
  - E.g. for Facebook
    - If user chose to keep Facebook, do nothing
    - If user chose to give up Facebook, then
      1. Ask them to give it up for 1 month
      2. After 1 month, verify whether they have used Facebook in the past month and reward them with \$W
  - This can be done remotely: Facebook reports when user was last online
  - Random application to 1 in 200 users suffices for Incentive compatibility

# Facebook study with Incentive Compatibility

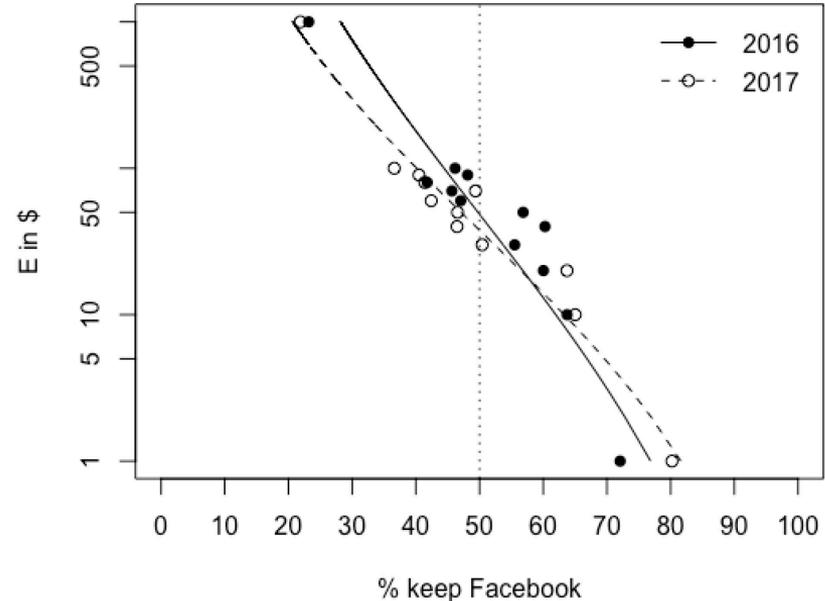

$n_{2016} = 1497, n_{2017} = 1388$

Median WTA: 2017    \$37.76 / month  
                                  [\$27.19, \$51.97]

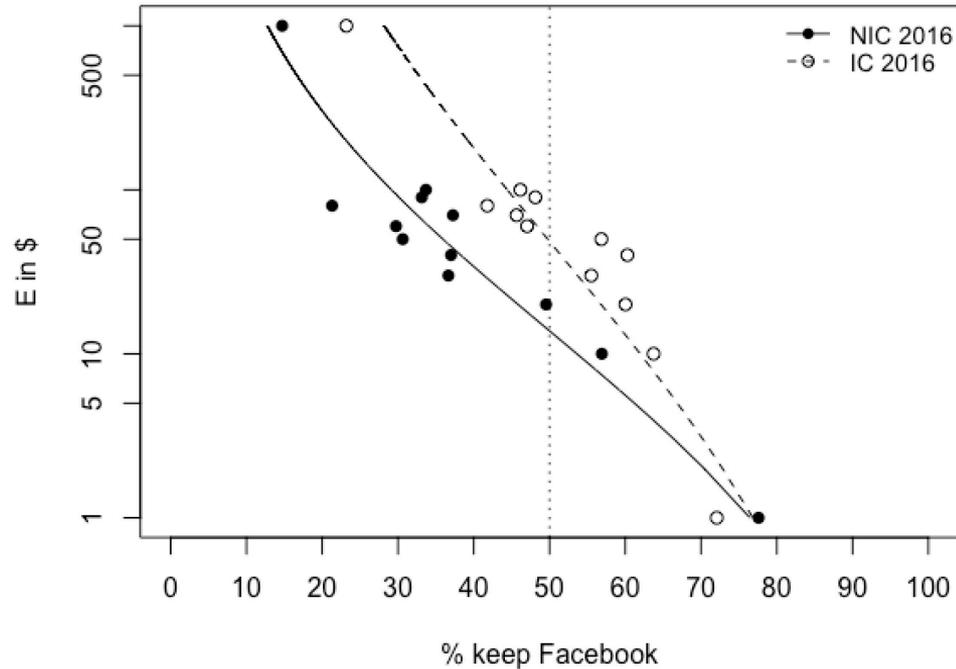

## Heterogeneity in valuation

Higher valuations for people with

- More time spent on Facebook
- More friends they have
- More frequent posting
- More videos watched
- Female
- Older
- Less use of Instagram or Youtube

# Relaxing Incentive Compatibility

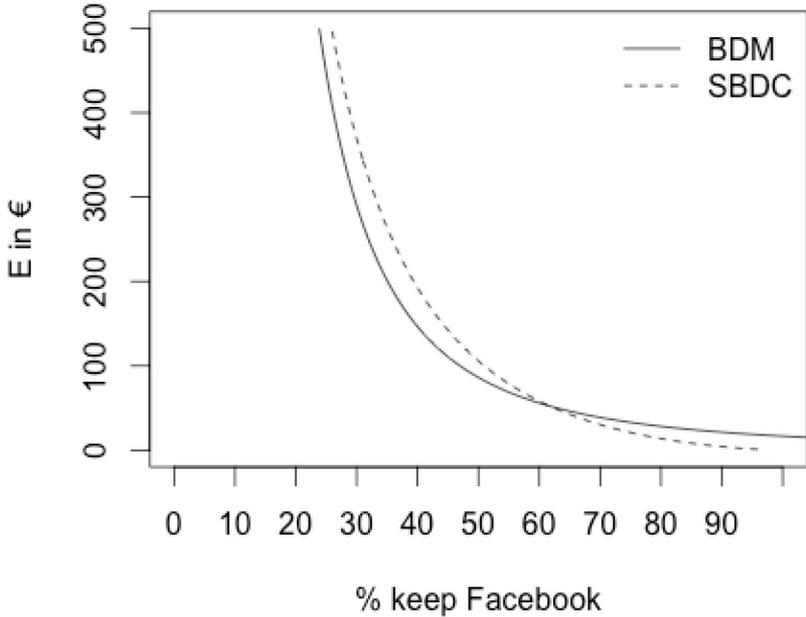

Values are *lower* for NIC condition => NIC is an underestimate

## Use Approach of Becker, DeGroot, and Marschak 1964

1. We ask minimum amount of money they would accept to give up Facebook for 1 month
2. After the survey, a random price is drawn from a uniform distribution of values.
  - If the random price is lower than the bid, the respondent will receive no money but can keep the access to Facebook.
  - If the random price is higher than the bid, the respondent will be paid the random price when giving up Facebook for 1 month.
    - We can remotely monitor whether they access Facebook for that month

# SBDC vs. BDM

N = 139 (BDM) and 356 (SBDC)

Observed shares between SBDC and BDM correlate strongly (Correl. = 0.891)

# Scale up using Google Consumer Surveys (NIC)

# BWS Results: Disutility from losing access to goods for 1 year

- Strong correlation (0.87) between SBDC WTA and BWS utilities
- Almost identical ordering between both approaches

# Integrating GDP growth accounting for free goods

## **Brynjolfsson, Diewert, Eggers, Fox & Gannamaneni (2017):**

- Derive an explicit term to measure the value of a free good on welfare change
  - Provide adjustments to national accounts to infer welfare from GDP
- Combine this framework with our choice experiments to empirically estimate adjustments to national accounts to include free digital goods

# GDP growth accounting for new and free goods

$$Q_{Full}^A = Q^F$$

$$+ (p_0^{0*} - p_0^1)q_0^1/[p^0 \cdot q^0 (1+PF)]$$

$$+ (w_0^{0*} - w_0^1)z_0^1/[p^0 \cdot q^0 (1+PF)]$$

$$+ [2w_0^1 \cdot (z^1 - z^0) + (w^1 - w^0) \cdot (z^1 - z^0) + 2w_0^1 z_0^1] / [p^0 \cdot q^0 (1+PF)]$$

→ adjustment for new goods

→ adjustment for new free goods

→ adjustment for continuing free goods

Where

$w^0$  = WTA of continuing free goods in period 0

$w^1$  = WTA of continuing free goods in period 1

$z^0$  = Quantity of continuing free goods in period 0

$z^1$  = Quantity of continuing free goods in period 1

$w_0^{0*}$  = Shadow WTA of new free good in period 0

$w_0^1$  = WTA of new free good in period 1

$z_0^1$  = Quantity of new free good in period 1

$p^0$  = Prices of non-free continuing goods in period 0

$q^0$  = Quantities of non-free continuing goods in period 0

$PF$  = Fisher price index =  $[(p^1 \cdot q^0 / p^0 \cdot q^0)(p^1 \cdot q^1 / p^0 \cdot q^1)]^{1/2}$

$w^t, z^t$  = WTA and quantity of free goods in period t

→ Estimated through choice experiments

# Conclusion

1. GDP, developed in 1930s, remains the de facto metric of economic growth.
2. Conceptually, consumer surplus is a better metric of well-being.
3. Massive online surveys have the potential to reinvent and significantly supplement the measurement of economic welfare.
  - Can be used for goods whether they have zero price or positive price
  - Highly scalable
  - Can be run in near real time to track changes in well-being
4. This approach can be incorporated into the national accounts

# Can We Incorporate This Into the National Accounts?

- **For goods which have a price:**
  - We can often infer welfare from national accounts
    - Consider effects of changes in prices and quantities on welfare
  - E.g. Hulten 1978, Diewert 1983, Jorgenson and Slesnick 2014, and others.
- **For new goods:**
  - Try to estimate virtual price (aka shadow or reference price) in pre-launch period which would imply 0 units of consumption
    - Then infer welfare using similar methods
  - E.g. Hicks 1920, Diewert 1980, Hausman 1994, Feenstra 1994
- **Other issues to consider:**
  - Intangibles, quality adjustments, household production etc.
- **Many alternative indexes for happiness, subjective well-being etc.**

**Challenge: Integrate free goods**
